To help the aspiring contributor, this document presents a manuscript from *Science and Children* with boxed explanations of the main elements in the text. While successful articles can be structured in various ways, this example may serve as one possible model to help you organize your own manuscript to make it more publishable. This feature article describes a lesson presented in an elementary classroom. This is the mainstay of S&C, representing the majority of our articles. However, you may want to consider writing a column. See our call for papers for column descriptions. Before you begin writing your article, please review our author guidelines and read several S&C feature articles—note the variety of ways authors chose to structure them.

**Title:** Stalk It Up to Integrated Learning

**Subtitle:** Using foods we eat and informational texts to learn about plant parts and their functions

The title provides enough information to inform the readers of the main idea of the article. It is brief, allowing it to be given large type treatment in layout.

Subtitles provide more details about the article. These components are also used to identify articles through search engines.

The diet of many students consists of on-the-go processed food. As part of a larger school garden project, we wanted students to consider the relevance of plants in their own lives, both as food sources for us and for the animals that we eat. In this article, we present a mini-unit we taught in a third-grade classroom that helped students connect their developing ideas about plant parts with the plants we eat. This series of lessons were designed to integrate the use of informational texts into an inquiry-based science unit to meet both Common Core State Standards for English Language Arts and the *Next Generation Science Standards*. The classroom in which we worked is in a state that has not adopted the *Next Generation Science Standards*. The state’s science curriculum standards address plant structure and function in the third grade, whereas the NGSS address it in grade four.

The introduction should be brief and provide background concerning the development of the strategies and the grade level at which the lessons were presented. This is a good location to discuss the importance of the subject. Statistical evidence may be used, connections to standards explained, or a brief historical context given. Note that although state standards may be important in the development of lessons, they should only be briefly mentioned and not
be the focus of the article. Additional paragraphs in this section may include describing a shortcoming or misconception the author has observed in class and how the article addresses that; sketching a brief narrative scene including the type of school, special needs addressed, and support of other agencies; or an explanation of the pedagogy that supports the strategies used. Consider what elements are important to highlight at the beginning and expanded further later in the article.

Subhead: Introducing Plant Parts

The main body of the article begins with a subhead. Subheadings provide an indication of steps in a process, the continuum of learning, important ideas that are addressed, or other indicators that will support the reader as they move through the article and revisit it in the future. Many S&C articles follow a 5E learning cycle—Engage, Explore, Explain, Elaborate, and Evaluate—and use these phases as subheadings.

A sprouting onion or a potato is an indication that plants that we eat are part of a larger plant. Though students may be used to seeing onions in the grocery store or at home, they often are seeing only the bulb, one part of a plant disconnected from the full plant that it came from. To begin our unit, we held up a sprouting onion and asked the class: “What is happening to this onion?” To focus the conversation on plant parts, we asked the students questions such as: Is this a plant? How do you know? What parts of a plant can you see? Are there any parts missing? For the parts of the plant that you do see, what do these parts help the plant to do? During this initial conversation, we made a list of the parts of plants that students knew on the board. The parts we were looking for were: leaf, stem, root, flower, and fruit. The students were able to name all five. Creating a list of the plant parts that students could refer to during the lesson is one way that we were scaffolding scientific language for English Language Learners in the classroom. From the discussion above, students seemed comfortable with the idea that many food plants had stems, roots, and leaves, but were less sure that these plants would also have flowers and fruits.

Many articles begin with a preassessment or a vignette that gives a sense of what ideas students are bringing to the learning experience. In other cases, it may begin with additional background concerning the how and why of lesson development.

Note the use of direct quotations. In this case, questions are made directly to students. Direct quotes lend authenticity and variety to the manuscript. Also use quotations from students as they engage with the activity. This will support your writing and providing a peek into your classroom.
As a preassessment, we gave students a photo of a tomato plant and asked them to label each part of the tomato plant that they could see using the list we had generated on the whiteboard. If they thought there was a part they could not see, they were to draw the missing part on the photo. The tomato plant photo had all of the parts of a tomato plant visible except the roots. In the preassessment, most students were able to label the stems, leaves, about half labeled the fruit and flowers, but only about a third drew roots coming from the main stem of the plant.

---

**Although this article does not require background information to help the reader understand disciplinary core ideas, when applicable, this information may be provided either within the text or separately in a sidebar.**

---

After students completed their labeling of the photo of a tomato plant, they were ready for an investigation of other food plants. The classroom teacher split the students into groups of four. We wanted to provide students with one example of a food plant that people eat from each of the five different categories of plant parts listed in our state curriculum standards. These included cabbage (leaf), radish (root), tomato (fruit), broccoli (flower), and celery (stem). {! insert safety symbol} For safety reasons, send home a letter to parents before the beginning of the unit to confirm any food allergies students may have before buying your food plant examples.

---

**It’s imperative to include safety notes concerning awareness of how the environment, substances, and equipment might be dangerous and how these hazards were addressed, such as the use of safety goggles (See www.nsta.org/safety for guidelines).**

---

Having students work with physical parts of food plants in cooperative learning groups is a strategy that benefits English Language Learners. Working with *realia*, classifying the food plants into one of the five parts listed on the board, and conversing with fellow students are strategies to develop oral scientific discourse before asking students to read or write with scientific language. These strategies benefit ELL students (Gibbons 2014) as well as students with special needs (Sorel 2003).

---

**When a claim is made, a reference should accompany it that provides evidence in support of the claim.**
Each group of four students received a basket with hand lenses and five food plants packaged as they would be found at the grocery store. We chose plants that came in packages with multiples for maximum cost effectiveness. The groups were given a few minutes to go through the basket to look at the examples and identify each of the plants by name. Then, each student was given a data recording sheet with the list of food plants (Table 1, see NSTA Connection).

| Provide data sheets, templates, sample letters to parents, examples of student work, assessment tools, rubrics, and as many images of students at work as possible. Some may be published with your article, and many of these items will be added to the NSTA online resource collection. |

We asked students to make observations using their hand lenses and to make predictions about what part of the whole plant each food was. We modeled for the class how to do this with an asparagus spear. As a whole class, students discussed what part of the plant they thought an asparagus spear was and why, while we showed them on the projector using an example data sheet where to fill in this information. Students went back to their small groups to work through their predictions for the five food plant examples in their basket. They only completed the first two columns of the table during this part of the lesson.

| Details are added to indicate how student learning is supported. This provides a clear picture for the reader concerning what they might anticipate encountering as they adapt the activity for their own classroom. |

As students worked, we walked around to the groups to see what their predictions were and what observations they were making about the plants to use as evidence to support their predictions. Questions we asked included: Why do you think the radish looks like a root? What do you see? What do you feel? We encouraged them to focus on using the plant part’s characteristics as evidence. In this way, we were encouraging students to make their predictions using evidence to support their argument, which is the associated scientific and engineering practice associated with the disciplinary core idea LS1A.

| Instead of detailing the NGSS connection, it is mentioned here with the connection expanded upon at the end of the article in the NGSS connections box. Find out more in the author guidelines and download a NGSS connections template. |

This aspect of the activity also becomes an opportunity for formative assessment of student ideas about plants and their parts. Student responses gave us insight into some possible
misconceptions that they had about plants we eat. Example answers focusing on characteristics of the radish included: “because the bottom looks like a string,” “because it’s hairy,” and “because it’s got a root.” When we did not ask these prompting questions, students wrote down answers based on their previous experiences and observations about plants that we eat. For example, some students wrote down “fruit” for each food plant, while a couple others wrote down “vegetable” for each one, both writing “because we eat it” as their evidence.

Providing additional questions and student responses is another tool used to help the reader understand how they might proceed with their lesson development. 
Note the frequent use of formative assessment. The identification of formative assessment validates student learning and the value of the lessons.

When students had finished making their observations and predictions, we gave each group multiple copies of *The Vegetables We Eat* by Gail Gibbons (2007), to use to check their predictions. At this point in the lesson, students used the text to complete the final two columns in Table 1. Having students use an informational text to find confirmation for or corrections to their classifications addresses an English Language Arts Key Ideas and Details standard (CSS.ELA-Literacy.RI.4.1). While students were looking through the book to find information, we walked around to ask them questions about what they were reading, such as: *What are some other leaves that we eat? Looking at the broccoli now, why do you think the book says that it’s a flower bud?* Then, using the example data recording sheet on the document camera, we asked the students in a whole-class discussion to tell us what they found out in their book. We reviewed the correct identification of the plants’ parts, as well as which examples were surprising to students and why. Students were surprised that tomatoes were considered a fruit, when they are not sweet and are called a vegetable in other contexts. Other students mentioned that they were surprised that broccoli was a cluster of flower buds because many of the students had never seen a broccoli plant in bloom. Reviewing the physical plant parts with their corresponding classifications as stems, roots, leaves, flowers, or fruits is an important reinforcement of the correct use of scientific language for English Language Learners (Gibbons 2014).

In addition to identifying connections to NGSS, you may identify connections to Common Core ELA main ideas, Math standards, or other national standards that are a focus of the article.
After a discussion of all of the examples, we asked students to go back to their labeled photos of the tomato plant from the beginning of the lesson to see if they wanted to change their answers about which parts they labeled. Relabeling their photo of the tomato plant served as a formative assessment that revealed whether students were able to correctly identify the five plant parts in one food plant example. As an alternative formative assessment for more advanced students, you could have students observe a corn cob that you bring to class, as well as a photo of a corn plant, to see if they could label all five plant parts on the photograph of a new plant.

Digging Deeper
On day two, we reviewed with students the parts of the plants that we had observed on Day 1. Then, we split students into groups of six. Each group of six students received three copies of a book about their plant part with the task of becoming an expert on that part (see Resources). Students used a reading prompt sheet (see NSTA Connection) with questions developed using the Question-Answer-Relationship (QAR) questioning strategy (Jones and Leahy 2006) for them to answer about their plant part, thus giving them a purpose when reading their informational text. Students had previously reviewed this QAR reading strategy with their third-grade classroom teacher. In pairs, students used their book to find information about their plant part, searching for key ideas and details (CCSS.ELA-Literacy.RI.4.1) to answer the Right There and Think and Search questions. Students also needed to interpret diagrams, photographs, and text in answering the Think and Search and the Author and Me questions (CCSS.ELA-Literacy.RI.4.7). We walked around to the groups to help them make sense of the information they were reading, for example, helping them with vocabulary words they did not know or prompting them to look more closely at photographs to help with context clues. We encouraged them to share with each other in their groups the information that they found out about their plant part in preparation to be an “expert.” By reading and discussing the text in pairs in their group of six, English Language Learners and native speakers of varying reading abilities are able to help each other prepare for their future role as experts on their plant part and its function.

Support for students with special needs is identified—in this case, English Language learners.
When they finished their “expert” research, the students were put into their new jigsaw groups to report the results of their informational reading. Each jigsaw group had a student who was an “expert” on leaves, another who was an “expert” on flowers, another who was an “expert” on stems, and so on.

*Note the mention throughout the article of a variety of groupings in which students participate, once again, this helps the reader picture what might work in their classroom.*

Students then shared what they had learned about their part of the plant and what it helped the plant to do. In this type of discussion, students must draw on their prepared information (CCSS.ELA-Literacy.SL.4.1.A) to communicate specific ideas about the plant parts and their function (CCSS.ELA-Literacy.SL.4.1.D).

After the jigsaw discussions, we came back together as a whole class to reinforce the functions of each of the plant parts students had been discussing, as shown in Table 2. In this discussion, we specifically wanted students to recognize common characteristics of the plant parts and how these might be related to their function in a plant. For example, some students noticed that radishes had “strings” or “hairs” on them. We talked about whether or not they thought all roots might have these features and how these hairs might help the root achieve its function to absorb water and nutrients from the soil. This discussion amongst the teacher and student experts was an opportunity to emphasize how each part of the plant plays an important role in the survival, growth, and, in the case of fruit and flower, reproduction (disciplinary core idea LS1A).

*Specific learning goals are identified to help explain why specific steps are taken in the lesson.*

Further activities that could follow this mini-unit might be planting of carrot seeds to observe the plant grow over time. When observing a plant like a carrot through its life cycle, students have an opportunity to see how they might eat the root of a plant, but that plant still has a stem, leaves, flowers, and fruits. In their school garden, students had the opportunity to observe lettuce, potatoes, peas, garlic, and radishes grow during the school year, thus providing them with various plant parts that people depend on to eat. Teachers without access to a school garden could have students start some of these plants as seeds in their classrooms under a grow light to observe the life cycle. Plants like lettuce, beans, and radishes work especially well as classroom
plants (Piotrowski, Mildenstein, Dungan, and Brewer 2007). Discussing simple recipes that students could use with their parents for the preparation of the food plant that they have grown in the classroom is an opportunity to help them think about how to use plants in a less processed diet.

After completing this mini-unit and following up with hands-on experiences observing a plant grow through its life cycle, students are on their way to having the foundational knowledge needed to meet the performance expectations cited in the NGSS in which they must “construct an argument” connecting a “macroscopic” structure of a plant to its function (i.e., roots, stems, leaves, flowers, fruits, and seeds) (NGSS Lead States 2013, p. 38).

Finally, the students in this lesson not only learned about plant parts, but were involved in using informational texts for an authentic purpose: gathering science information to compare with their observations. This authentic use of informational texts in a science context can be leveraged to review text features, reading for information strategies, reading comprehension, and communication of information to address English Language Arts Common Core Standards. We found that when students are motivated to read for information related to a recent concrete science experience, they are engaged in the work and eager to learn more. The science and English language arts learning is more robust when integrated together in a relevant context for students. Stalk it up to the integration!
